Introduction

Too cold and windy environmental conditions represent the most common reason for commuters not to go to work by bike (Sears et al., 2012). Footwear plays a key role for the overall thermal comfort in cold environment. Cold feet represent a symptom of general cold discomfort (Kuklane, 2013). If the insulation properties of the clothing system are inadequate and athletes feel cold, they will often perceive it in the feet.

The overall goal of the research project was to improve an existing winter cycling shoe towards optimised thermal comfort – also considering the influence of headwind on skin foot temperature. In a first step a computational fluid dynamic analyses (CFD) were performed to detect the influence of headwind on defined foot regions at three different pedal/foot positions. These findings should be implemented in the further development of the new shoe model. In a second step the newly developed winter cycling shoe should be evaluated within a subject study by means of thermal imaging and subjective perception.

Material & Method: CFD analyses were done at AirShaper™ using a steady-state RANS (Reynolds Averaged Navier Stokes) method with k-omega SST turbulence model. The boundary conditions used are: wind speed: 5.5 ms⁻¹; air temperature: 15°C, air density: 1.225 kgm⁻³; atmospheric pressure: 101300 Pa. The focus of this study was on the lower leg. The three analysed pedal/foot positions (Fig. 2) were derived from Broker (2003). The qualitative evaluation of the simulation was focused on the general flow patterns (3D trajectories of “air particles”) and the pressure and velocity profiles around the foot. 3D wake patterns (iso-surfaces for a total pressure equal to zero) were also considered. Local surface pressure and surface streamlines were used as the prime indicator for possible air penetration through the upper material.

Material & Method: Four male bike commuters (37±10 years; 176±0.1 cm; 76±11 kg) participated on the subject study. They performed a load profile of 30 min. cycling on a Tacx cycling trainer at 120W. Each subject had to cycle in 2 benchmark models and in the old vs. new Vaude cycling shoe (Fig. 3).

The subjects were tested in a climate chamber at 0±1°C and ~90% relative humidity. Two floor fans were positioned in front of the cyclist generating an airflow aimed at the lower legs of the cyclist. An infrared camera (FLIR E85) was used to determine surface temperature. The barefoot IR images and subjective feedback were taken just before and after the cycling activity.

Results: The new Vaude shoe indicates the lowest temperature loss and hence the best insulation characteristics within the tested footwear conditions (Fig. 4). The old Vaude model and Northwave exhibit a substantially higher temperature loss of more than 2°C. The thermal images (Fig. 5) of all 4 tested footwear conditions clearly indicate the toe area as the anatomical location with the lowest skin temperature and thus the most vulnerable region to suffer from cold thermal discomfort.

Discussion & Conclusion

There is only little research available on thermal comfort of athletic footwear in cold weather conditions. However, studies which investigated the thermal comfort of ski boots emphasise the importance of insulation properties and wind resistance (Hofer et al., 2014). In addition, Hofer et al. (2014) point out the importance of keeping the feet and particularly the toes warm during skiing. This goes hand in hand with the present CFD results and the findings based on thermal imaging. The findings of both CFD analyses and subject study clearly illustrate that the dorsum of the foot and especially the toe region is most susceptible for thermal comfort during cycling in cold weather conditions. In that context appropriate footwear should offer optimal insulation properties and protection against wind and moisture. However, not only the material and the design of the footwear but also the whole footSock footwear system should be considered when optimizing the thermal foot comfort. The material and design interventions applied to the new Vaude shoe clearly confirm the opportunity to improve the thermal comfort, which was not only based on objective data but also on subjective feedback.
